A Simulated outbreaks: the epinowcast generative model

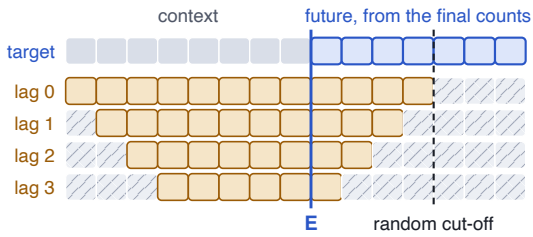

Each outbreak gives a daily reporting triangle by stratum (count by onset day and report day), also summed to weeks, with the total over strata.

B The reporting triangle as ragged series for Chronos-2

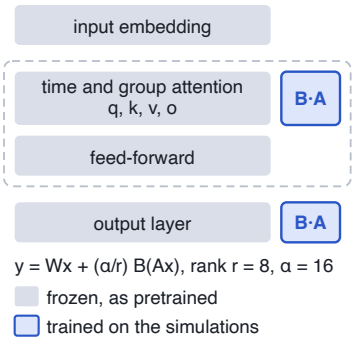

C Training blocks and LoRA fine-tuning

One block cut from a simulated release history

Each outbreak gives several weekly and daily blocks, each with a random cut-off, delay D and set of places. Daily blocks keep weekly releases, so their lag series have a value once a week. Checkpoints are trained on nested sets of simulated outbreaks.

LoRA: a frozen model, small trained adapters

Why it is fast

about 1.2M of 120M weights trained (1%)

- no gradients or optimiser state for the frozen backbone
- adapter about 5 MB, model about 0.5 GB
- trained once on a laptop GPU, reused for every forecast

D Forecasting with the fine-tuned model
